

Use of Propensity Score Matching

A thought exercise

Annette E. Ghee, PhD, MPH
 American Evaluation Association, Denver, CO

What is PSM designed for?

Asking Causal Questions without Randomized Experiments

Lack of →

- Random assignment does prevent us from asking causal questions, it just makes it difficult to make those inferences
 - Do patients in a residential rehabilitation center benefit from having a room with view? [1]
 - Do children who are instructed by teachers who specialize in PE have better physical fitness development than those taught by generalist teachers? [2]
 - How is sleep quality affected by stress among high school students? [3]
 - How did the September 11th attacks affect the mental health of British citizens? [4]

Our agenda today

- What issue was PSM designed to address?
- What are some pitfalls to keep in mind?
- How do you choose covariates that would ideally be used to create the Propensity Score?
- For those with experience, what have you learned from using it?

17-Oct-14 1

Making Causal Inferences

- Randomized experiments allow evaluators to control temporal precedence and reduce extraneous errors.
 - Therefore, these designs often provide unbiased estimates.
- Random assignment is not always practical in field settings
 - Ethical reasons (denying access to those who need Tx)
 - Logistical limitations (Can't separate participants)
 - Lack of cooperation from stakeholders (controlling Tx may be disruptive in settings)

What is a propensity score?

- A propensity score is the conditional probability of a unit being assigned to a particular study condition given a set of observed covariates [6].
- $pr(z = 1 | x)$ is the probability of being in the treatment condition
 - In a randomized experiment $pr(z = 1 | x)$ is known
 - It equals .5 in designs with two groups and where each unit has an equal chance of receiving treatment
 - In non-randomized experiments the $pr(z = 1 | x)$ is unknown and has to be estimated.

How can it be used?

- These scores can be used to equate groups on observed covariates through
 - Matching
 - Stratification (subclassification or blocking)
 - Weighting
 - Covariate adjustment (analysis of covariance or regression)
- Propensity score adjustments should reduce the bias created by nonrandom assignment, making those adjusted estimates closer to those effects from a randomized experiment [7].

17-Oct-14

World Vision

When should it be used?

- With quasi-experiments
 - When the independent variable was manipulated
 - When the intervention was presented before the outcome
- When the selection method is unknown
 - If assignment is based on a criterion, consider using a regression discontinuity design instead
- When there are several covariates related to selection
 - These can be continuous or categorical
 - The goal is to balance groups, so covariates should be related to selection
- The distribution of the dependent variable is unlimited
 - The adjustment analysis will vary based on the distribution

World Vision

Important limitations to consider

- Requires large data sets; matching requires cases to be dropped from analysis.
- Still subject to participation bias associated with unmeasured/able characteristics; must assume there is none but this is a strong assumption
- Assumes missing information is missing at random
- How does it affect external validity?

17-Oct-14 9

World Vision

How do you implement?

- Trying to mimic a randomized design
- We architect the analysis so that members of the comparison group have similar propensities to members of the treatment group
- The matched nature of the intent must be followed through in the analytic methods used. The difference in outcomes (Y) between treatment units and their matched comparison unit is the estimate of program impact.
- Covariates should be “balanced” after matching.

World Vision

World Vision Case Study

- Child Health Targets Impact Study (chTIS)
- Primary evaluation question
Does the World Vision package of community-based health programming have a beneficial effect (effectiveness) on a range of child health and nutritional outcomes?
- 4 countries: Cambodia, Guatemala, Kenya & Zambia

17-Oct-14 10

World Vision

Potential challenge

- What if there is not a good match between a treatment and a comparison unit?

Lack of “overlap”

World Vision

Conceptual framework (Theory of Change)

```

    graph LR
      CIP[CIP] --> IBP[Improved Behavior and Practices]
      CIP --> IQHS[Improved Quality of Health Services]
      IBP --> IHO[Improved Health Outcomes]
      IQHS --> IHO
      IHO --> IMP[Impact]
  
```

Improved Behavior and Practices

- Maternal and child iron/folate coverage
- Improved maternal and child nutrition practices
- Maternal and child use of LLINs
- Family Planning, knowledge and practices
- Breastfeeding, and complementary feeding practices
- Delivery at health facility
- Essential newborn practices
- Care seeking for sick-child
- Hygienic practices (hand-washing and safe disposal of stools)

Improved Quality of Health Services

- Reduced stock-outs
- Improved availability of skilled healthcare staff
- Improved client satisfaction
- Improved facility-level management of childhood illnesses

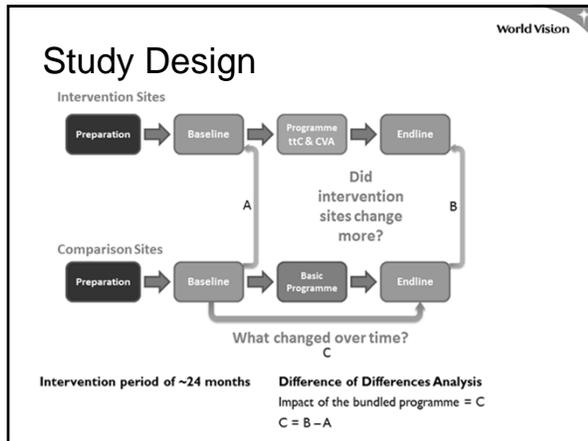

Improved Health Outcomes

- Ante-natal, skilled birth attendance coverage
- HIV testing
- Tetanus toxoid, anti-helminthic coverage
- Anemia in women and children
- Management of childhood illness (diarrhea, pneumonia, fever/malaria)
- Vaccination coverage
- Vitamin A supplementation

Impact

- Reduced Wasting
- Reduced underweight
- Reduced Stunting
- Reduced child morbidity
- Neonatal deaths averted
- Under-five deaths averted

Discussion

World Vision

Given that the covariates we select to compute the propensity score must be collected at baseline and that they should mimic criteria for random assignment...

- What covariates would you ideally like to use for this case?
- Ideally would you want them to be measured at the individual, household or community level?
- When you inspect a potential covariate you are considering including, what properties should you consider?

17-Oct-14 15

Important design considerations (?)

World Vision

- Is this really a treatment vs absence of treatment comparison?
- Will all eligible "beneficiaries" receive the World Vision program?
- Will all "beneficiaries" receive the same "dose" when exposed to the program?
- Will direct beneficiaries be identifiable/quantifiable?
